

Database

Hibernate causes trouble with shared databases

Several users have reported problems with shared network databases and hibernating. At this time, we do not recommend that you allow any PC hosting a shared database to hibernate. The other PCs need to lock database records, and the operation times out due to the hibernation - even if the hosting machine (the server) has been recently "awakened" from hibernation.

The ClipMate log may display an error such as

Microsoft SQL Server 8.0.2040 General Msg 8104: Cannot lock database with the table 'XXXX' (P)

Solution: PCs acting as database servers should never be allowed to hibernate.

Unique solution ID: #1068
